Sales datamart: transformed tables

Entity–relationship diagram for the tables emitted by the Beam normalization graph. The same schema is used by the local report checks and the configured BigQuery sink. PK means primary key; FK means foreign key.

Each customer can place many orders; each product can appear in many orders. Each order references exactly one customer and one product. The arrows point from each parent to its child table. A parent can have zero or many orders.

Integrity boundary. These are logical relationships checked by `reports.py` and `sql/bigquery.sql`, not automatically enforced BigQuery foreign-key constraints. The fixture intentionally contains one orphan customer reference; the check reports it, and inner-join reports exclude that order. Duplicate or conflicting source keys are resolved or rejected before this reporting stage.

Money. `price_cents` is the normalized integer-cent value, not the original raw price string. Revenue multiplies it by the order quantity with explicit numeric-range checks. No cloud execution is implied by this schema diagram.
